Chapter 7: Deadlocks

Chapter 7: Deadlocks

Chapter 7: Deadlocks

- System Model
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

Chapter Objectives

- To develop a description of deadlocks, which prevent sets of concurrent processes from completing their tasks
- To present a number of different methods for preventing or avoiding deadlocks in a computer system

System Model

- ☐ System consists of resources
- □ Resource types $R_1, R_2, ..., R_m$ CPU cycles, memory space, I/O devices
- Each resource type R_i has W_i instances.
- Each process utilizes a resource as follows:

```
□ request } her kannak by 3 a samadan Desen
□ use
□ release
```

Deadlock Characterization

Deadlock can arise if four conditions hold simultaneously.

- Mutual exclusion: only one process at a time can use a resource Bir Kaynak en fazla bir Process tarafından Kullanılması
- **Hold and wait:** a process holding at least one resource is waiting to acquire additional resources held by other processes P. elinde Kasnak var P2 nin elindeki Kasnas, bekliyar. Ancak P2 de Pi deki Kasnas, bekliyar. Ancak P2 de Pi deki Kasnas, olur.

 No preemption: a resource can be released only voluntarily
- by the process holding it, after that process has completed its task Processesin Kendine ayrılan kaynakları geri i ade etmemesi.
- Circular wait: there exists a set $\{P_0, P_1, ..., P_n\}$ of waiting processes such that P_0 is waiting for a resource that is held by P_1 , P_1 is waiting for a resource that is held by P_2 , ..., P_{n-1} is waiting for a resource that is held by P_n , and P_n is waiting for a resource that is held by P_0 . Hold and woith gill are d'ensisel.

 Note: Dew lock un olugnosi için bu 4 durum saglan mak Zorunda. aralarında AND ilişkisi var.

Deadlock with Mutex Locks

- Deadlocks can occur via system calls, locking, etc.
- □ See example box in text page 318 for mutex deadlock

Kernel içinde Deadlock oluşabiliyor.

Resource-Allocation Graph

A set of vertices V and a set of edges E. Yento $g \circ \uparrow$.

- V is partitioned into two types:
 - $P = \{P_1, P_2, ..., P_n\}, \text{ the set consisting of all the processes}$ in the system P_n $P(e^{e^{-\epsilon}})$
- I request edge directed edge $P_i \rightarrow R_j$ processten Kajnago edge P_i Request
- assignment edge directed edge $R_j \rightarrow P_i$ Kaynovitor processe edge $R_j \rightarrow P_i$ Kaynovitor processe edge $R_j \rightarrow P_i$

Resource-Allocation Graph (Cont.)

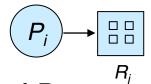

Process

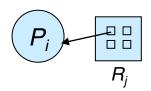

Resource Type with 4 instances

 \square P_i requests instance of R_i

 \square P_i is holding an instance of R_j

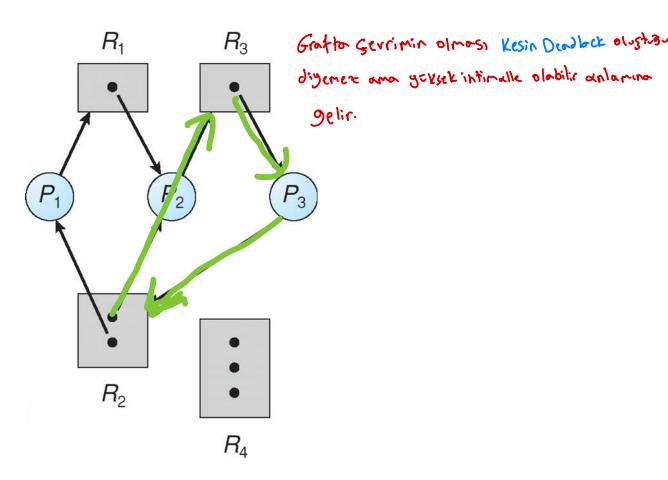

Example of a Resource Allocation Graph

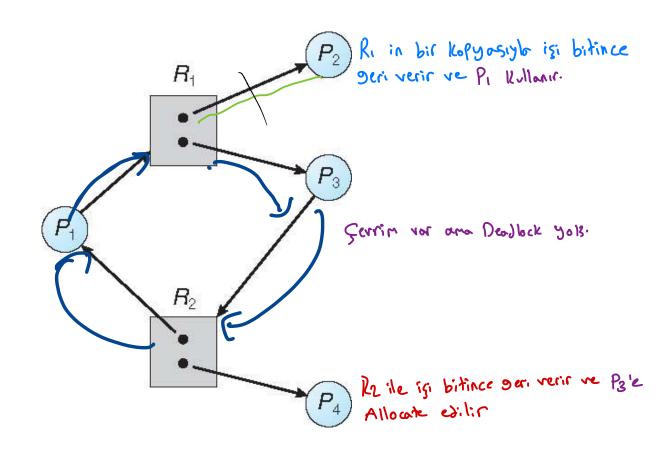

Resource Allocation Graph With A Deadlock

Graph With A Cycle But No Deadlock

Basic Facts

- □ If graph contains no cycles \Rightarrow no deadlock
- □ If graph contains a cycle \Rightarrow
 - □ if only one instance per resource type, then deadlock ולישאַ האַיּאַר אַפּראָבּעריי שפּיִּגּייי
 - if several instances per resource type, possibility of deadlock Kajnavlan Kalposi varso bir iktimalle var

Methods for Handling Deadlocks

Bir to Kin Kaynak ve Process.

- Ensure that the system will *never* enter a deadlock state:
 - Deadlock prevention ensellenck. Kaynakları Kısıtlı Kılanıyoz bozen Koynak boşta Kalabilir.
 - Deadlock avoidence Kaginnak. Beter Kaynaklar killange and her adindo Deadlock oluşurnu sorusuna yanış hesar yalarsak Dallock aluşabilir. Cevap vermek dirumundanyız.
- Allow the system to enter a deadlock state and then recover
- Ignore the problem and pretend that deadlocks never occur in the system; used by most operating systems, including UNIX

Deadlock Prevention

Restrain the ways request can be made

- Mutual Exclusion not required for sharable resources (e.g., read-only files); must hold for non-sharable resources για εκρικού εκτιλείτα εκπι ο εκγελεί διώλ.
 Hold and Wait must guarantee that whenever a process
- Hold and Wait must guarantee that whenever a process requests a resource, it does not hold any other resources
 - Require process to request and be allocated all its resources before it begins execution, or allow process to request resources only when the process has none allocated to it. intigaci olar beter kagnaklari we her all you hig almost
 - Low resource utilization; starvation possible ne kadar bekleyecely? starvation Koynak ayırdık and biz belki bişey hesafla sonra yazıcıyla yazdır. hesaflamor y sonra 2 sonra kullancasız? boşka kaynaklar Kullanan eyacaklar.

 Diğer Processler bu sefer biz bekleyeek.

Deadlock Prevention (Cont.)

- □ No Preemption Bir Processesin Konnomini Izni almadan clinden alinmostikenci bunu Sorunsuz yafabilir yafisi seresi
 - If a process that is holding some resources requests another resource that cannot be immediately allocated to it, then all resources currently being held are released
 - Preempted resources are added to the list of resources for which the process is waiting
 - Process will be restarted only when it can regain its old resources, as well as the new ones that it is requesting
- Circular Wait impose a total ordering of all resource types, and require that each process requests resources in an increasing order of enumeration

Kaynaxber Nunalander. Processler Koynaxları artan bi şekibe istemesi lazın Rs sonra Rox dma Process başlanadan hargi Sırayb hargi Kaynaxlara ihtiyaer

Ob Buro bilmesi lazım. Online-interactive sistemlerle Bu in Kansızdır.

Deadlock Example

```
/* thread one runs in this function */
void *do work one(void *param)
   pthread mutex lock(&first mutex);
   pthread mutex lock (&second mutex);
   /** * Do some work */
   pthread mutex unlock(&second mutex);
   pthread mutex unlock(&first mutex);
   pthread exit(0);
/* thread two runs in this function */
void *do work two(void *param)
   pthread mutex lock(&second mutex);
   pthread mutex lock(&first mutex);
   /** * Do some work */
   pthread mutex unlock(&first mutex);
   pthread mutex unlock(&second mutex);
   pthread exit(0);
```

Deadlock Example with Lock Ordering

```
void transaction(Account from, Account to, double amount)
{
    mutex lock1, lock2;
    lock1 = get_lock(from);
    lock2 = get_lock(to);
    acquire(lock1);
        acquire(lock2);
        withdraw(from, amount);
        deposit(to, amount);
        release(lock2);
    release(lock1);
}
```

Transactions 1 and 2 execute concurrently. Transaction 1 transfers \$25 from account A to account B, and Transaction 2 transfers \$50 from account B to account A

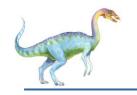

Deadlock Avoidance

Requires that the system has some additional *a priori* information available

- Simplest and most useful model requires that each process declare the *maximum number* of resources of each type that it may need her Process her Koyanktan en forch the Kador Kullanu onu Ser. Koyank istek sources.
- Resource-allocation state is defined by the number of available and allocated resources, and the maximum demands of the processes

Kongrander isterne snosinda neuert duruma 9 ère bu Kaynax tahsisati sistemi <u>Safe</u> durumunda Olur mu diye Kontrol eden ve Sistemi Safe durumunda tutmaya çalışır.

Safe State

- When a process requests an available resource, system must decide if immediate allocation leaves the system in a safe state
- System is in **safe state** if there exists a sequence $\langle P_1, P_2, ..., P_n \rangle$ of ALL the processes in the systems such that for each P_i , the resources that P_i can still request can be satisfied by currently available resources + resources held by all the P_i , with j < l
- That is:
 - If P_i resource needs are not immediately available, then P_i can wait until all P_i have finished
 - □ When P_j is finished, P_i can obtain needed resources, execute, return allocated resources, and terminate
 - □ When P_i terminates, P_{i+1} can obtain its needed resources, and so on

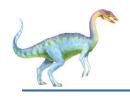

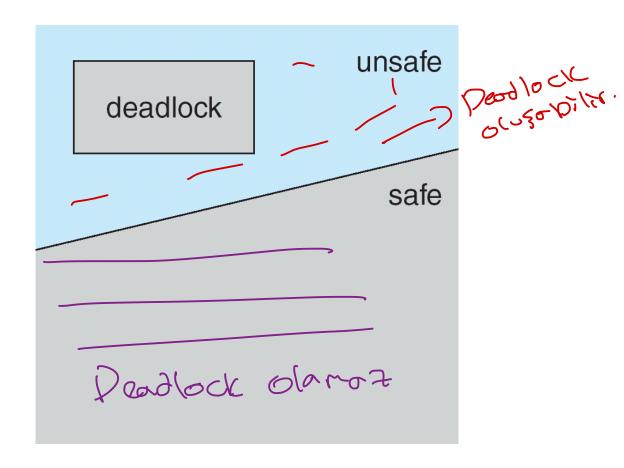

Basic Facts

- □ If a system is in safe state \Rightarrow no deadlocks
- If a system is in unsafe state \Rightarrow possibility of deadlock
- Avoidance ⇒ ensure that a system will never enter an unsafe state.

Safe, Unsafe, Deadlock State

Avoidance Algorithms

- ☐ Single instance of a resource type
 - Use a resource-allocation graph
- ☐ Multiple instances of a resource type Kosnowlan Kopyolon vor ise
 - Use the banker's algorithm

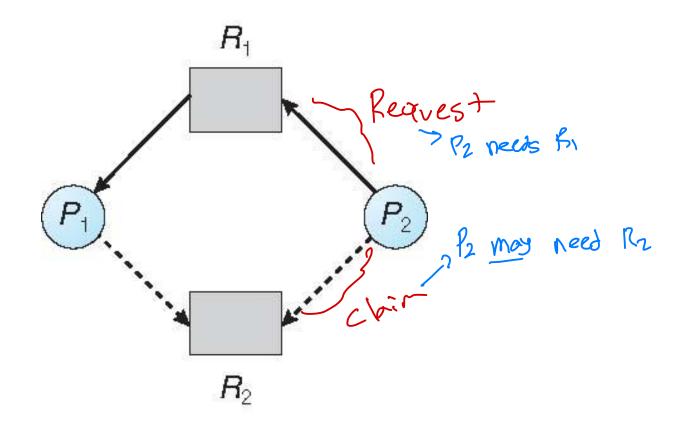

Resource-Allocation Graph Scheme

- □ Claim edge $P_i \rightarrow R_j$ indicated that process P_j may request resource R_i ; represented by a dashed line
- Claim edge converts to request edge when a process requests a resource
- Request edge converted to an assignment edge when the resource is allocated to the process
- When a resource is released by a process, assignment edge reconverts to a claim edge
- Resources must be claimed a priori in the system

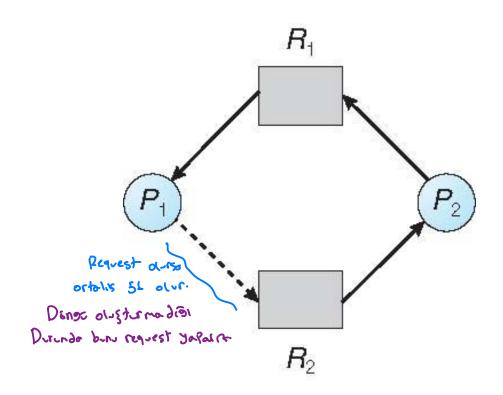

Resource-Allocation Graph

Unsafe State In Resource-Allocation Graph

Resource-Allocation Graph Algorithm

- \square Suppose that process P_i requests a resource R_i
- The request can be granted only if converting the request edge to an assignment edge does not result in the formation of a cycle in the resource allocation graph

Banker's Algorithm

- Multiple instances
- Each process must a priori claim maximum use yine mox he kador lazm one sayler
- When a process requests a resource it may have to wait
- When a process gets all its resources it must return them in a finite amount of time

```
Kaynakbu makul bir Zamanda gei dunderneli
```

Data Structures for the Banker's Algorithm

Let n = number of processes, and m = number of resources types.

- her Kaynagim Kos Kopyosi var bilgisini totan dizi.
- □ **Available**: Vector of length m. If available [j] = k, there are k instances of resource type R_i available
 - Processx Koynola modisi bir Process bir kaynossin enfazlo Kog Kopyosini Kullant onu total.
- □ Max: $n \times m$ matrix. If Max[i,j] = k, then process P_i may request at most k instances of resource type R_i
- Allocation: $n \times m$ matrix. If Allocation [i,j] = k then P_i is currently allocated k instances of R_i
- Dir Processin Bir Voyrov son intigoed Kolon Royrov sayısı.

 Need: $n \times m$ matrix. If Need[i,j] = k, then P_i may need k more instances of R_i to complete its task

Need[i,j] = Max[i,j] - Allocation[i,j]

Safety Algorithm

 Let Work and Finish be vectors of length m and n, respectively. Initialize:

Work = Available
Finish
$$[i]$$
 = false for $i = 0, 1, ..., n-1$

- 2. Find an *i* such that both:
 - (a) *Finish* [*i*] = *false*
 - (b) $Need_i \leq Work$ If no such i exists, go to step 4
- 3. Work = Work + Allocation; Finish[i] = true go to step 2
- 4. If *Finish* [i] == true for all i, then the system is in a safe state

Resource-Request Algorithm for Process P_i

Request_i = request vector for process P_i . If **Request**_i[j] = k then process P_i wants k instances of resource type R_j 1. If $Request_i \leq Need_i$ go to step 2. Otherwise, raise error condition,

- since process has exceeded its maximum claim

 2. If **Request**; \(\text{Available}, \) go to step 3. Otherwise P_i must wait, since resources are not available
- 3. Pretend to allocate requested resources to **P**_i by modifying the state as follows:

Available = Available - Request; - Kalon Kognak soyisin orasit Allocation; = Allocation; + Request; & Procase ayrilar Kayrok Suyisi Need; = Need; - Request; & Processin Kalanihaiyag Sayısın, azala

- □ If safe \Rightarrow the resources are allocated to P_i
- □ If unsafe $\Rightarrow P_i$ must wait, and the old resource-allocation state is restored

eger Degerter ben ursate store'a sok-yorsa son acongitar revert edilir.

Example of Banker's Algorithm

 \square 5 processes P_0 through P_4 ;

3 resource types:

A (10 instances), B (5instances), and C (7 instances)

Snapshot at time T_0 :

	<u>Allocation</u>	<u>Max</u>	<u>Available</u>
	ABC	ABC	ABC
P_0	010	753	332
P_1	200	322	532
P_2	302	902	743
P_3	211	222	745
P_4	002	433	-753

herbong, birmi his bir jezilde dog-rangorsad redlock valder

Example (Cont.)

☐ The content of the matrix *Need* is defined to be *Max – Allocation*

	<u>Need</u>	
	ABC	
P_0	7 4 3	
P_1	122	
P_2	600	
P_3	011	
P_4	431	

□ The system is in a safe state since the sequence $\langle P_1, P_3, P_4, P_2, P_0 \rangle$ satisfies safety criteria

Example: P_1 Request (1,0,2)

□ Check that Request \leq Available (that is, $(1,0,2) \leq (3,3,2) \Rightarrow$ true

	<u>Allocation</u>	<u>Need</u>	<u>Available</u>
	ABC	ABC	ABC
P_0	010	743	230
\ <u>P</u>	302	020	832
P_2	302	600	7 43
1-P3	211	011	7 45 785
\mathcal{P}_{4}	002	431	· • • • • • • • • • • • • • • • • • • •

- Executing safety algorithm shows that sequence $\langle P_1, P_3, P_4, P_0, P_2 \rangle$ satisfies safety requirement
- □ Can request for (3,3,0) by **P**₄ be granted?
- Can request for (0,2,0) by P₀ be granted?

Deadlock Detection

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

Single Instance of Each Resource Type

- □ Maintain wait-for graph resource allocation oration Donistorilais hali.
 - □ Nodes are processes > horsi Process horsi Processi bekliyor. Koynok yok.
 - $P_i \rightarrow P_j$ if P_i is waiting for P_j
- Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock

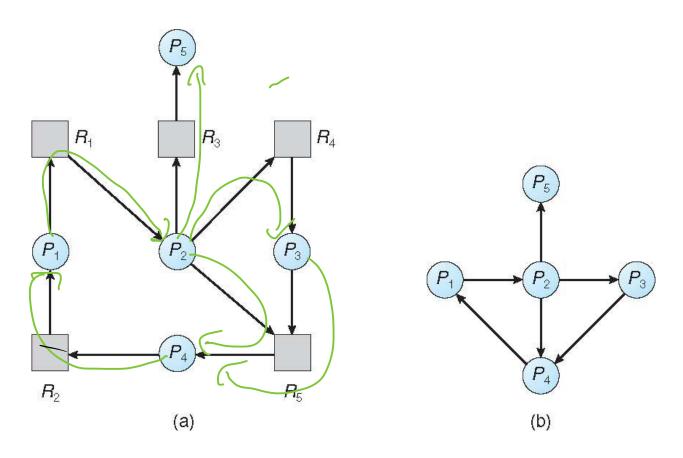

```
water gratinga Denos varise Mittaka Denos vardr.
```

An algorithm to detect a cycle in a graph requires an order of n^2 operations, where n is the number of vertices in the graph

Resource-Allocation Graph and Wait-for Graph

Resource-Allocation Graph

Corresponding wait-for graph

Several Instances of a Resource Type

- Available: A vector of length m indicates the number of available resources of each type
- □ Allocation: An n x m matrix defines the number of resources of each type currently allocated to each process
- Request: An $n \times m$ matrix indicates the current request of each process. If Request[i][j] = k, then process P_i is requesting k more instances of resource type R_i .

Detection Algorithm

- 1. Let **Work** and **Finish** be vectors of length **m** and **n**, respectively Initialize:
 - (a) Work = Available
 - (b) For i = 1,2, ..., n, if Allocation_i ≠ 0, then Finish[i] = false; otherwise, Finish[i] = true
- 2. Find an index *i* such that both:
 - (a) Finish[i] == false
 - (b) *Request_i* ≤ *Work*

If no such *i* exists, go to step 4

Detection Algorithm (Cont.)

- 3. Work = Work + Allocation_i
 Finish[i] = true
 go to step 2
- 4. If *Finish[i]* == *false*, for some i, $1 \le i \le n$, then the system is in deadlock state. Moreover, if *Finish[i]* == *false*, then P_i is deadlocked

Algorithm requires an order of $O(m \times n^2)$ operations to detect whether the system is in deadlocked state

Example of Detection Algorithm

- Five processes P_0 through P_4 ; three resource types A (7 instances), B (2 instances), and C (6 instances)
- \square Snapshot at time T_0 :

	<u>Allocation</u>	<u>Request</u>	<u>Available</u>
	ABC	ABC	ABC
P_0	010	000	000
P_1	200	202	
P_2	303	000	
P_3	211	100	
P_4	002	002	

 \square Sequence $\langle P_0, P_2, P_3, P_1, P_4 \rangle$ will result in *Finish[i] = true* for all *i*

Example (Cont.)

P₂ requests an additional instance of type C

$\frac{Request}{A B C}$ $P_0 = 0.00$ $P_1 = 2.02$ $P_2 = 0.01$ $P_3 = 1.00$ $P_4 = 0.02$

- □ State of system?
 - \square Can reclaim resources held by process P_0 , but insufficient resources to fulfill other processes; requests
 - Deadlock exists, consisting of processes P₁, P₂, P₃, and P₄

Detection-Algorithm Usage

- When, and how often, to invoke depends on:
 - How often a deadlock is likely to occur?
 - How many processes will need to be rolled back?
 - one for each disjoint cycle
- If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes "caused" the deadlock.

Recovery from Deadlock: Process Termination

- Abort all deadlocked processes
- Abort one process at a time until the deadlock cycle is eliminated
- In which order should we choose to abort?
 - 1. Priority of the process
 - How long process has computed, and how much longer to completion
 - Resources the process has used
 - 4. Resources process needs to complete
 - 5. How many processes will need to be terminated
 - 6. Is process interactive or batch?

Recovery from Deadlock: Resource Preemption

- Selecting a victim minimize cost
- Rollback return to some safe state, restart process for that state
- Starvation same process may always be picked as victim, include number of rollback in cost factor

End of Chapter 7
